Thanks, I thought I had kicked the demo around but I guess I never got screen shots.

@SomeGuy
I took a bunch of screenshots, hopefully you got enough time to add them. This demo looks awesome

One of the most significant factors affecting real-time response is the operating system's task switch time and speed of inter-task communication.

How long it takes to change from running one program to another.

A simple program which passes a one-byte message between two tasks was benchmarked on a number of systems. QNX has proven unsurpassed in this critical area.

QNX will run on PC's, AT's and all the PS/2's. You can run it in REAL or PROTECTED mode. You can connect any mix of machines together in a local area network and run the same commands on any machine. QNX will run quite comfortably in a 320K machine. In protected mode this can be expanded to 16 Megabytes. Even on a small PC you still get full multi-tasking, multi-user (both attached terminals and windows) as well as a fully integrated local area network. QNX's real time speed often has it outperforming the competition on PC's when they are running on AT's. QNX is truly in a class by itself.

(I really like the bit bucket. Years ago I wrote a Linux kernel driver for such a device from signetics https://github.com/spacerace/write-only-memory)
